Order-1 encoding

To encode Order-1 statistics typically requires a larger table as for an N sized alphabet we need to potentially store an $N \times N$ matrix. We store these as a series of Order-0 tables.

We start with the outer context byte, emitting the symbol if it is non-zero frequency. We perform the same run-length-encoding as we use for the Order-0 table and end the contexts with a nul byte. After each context byte we emit the Order-0 table relating to that context.

One last caveat is that we have no context for the first byte in the data stream (in fact for 4 equally spaced starting points, see "interleaving" below). We use the ASCII value ($(\0)$) as the starting context for each interleaved rANS state and so need to consider this in our frequency table.

Consider abracadabraab

Naively observed Order-1 frequencies:

Normalised (per Order-0 statistics):

Context	Symbol	Frequency
$\setminus 0$	a	4
a	a	3
	b	8
	с	4
	d	<u>4-5</u>
b	r	8
с	a	4
d	a	4
r	a	7-8

Context	Symbol	Frequency
$\setminus 0$	a	4095
a	a	646 -614
	b	1725 - 1639
	с	862 -819
	d	862 - <u>1023</u>
b	r	4095
с	a	4095
d	a	4095
r	a	4095

Note that the above table has redundant entries. While our complete string had three cases of two consecutive "a" characters ("...cadabr**aa**braca..."), these spanned the junction of our split streams and each rANS state is operating independently, starting with the same last character of nul (0). Hence during decode we will not need to access the table for the frequency of "a" in the context of a previous "a". A similar issue occurs for the very last byte used for each rANS state, which will not be used as a context. In extreme cases this may even be the only time that symbols occurs anywhere. While these scenarios represent unnecessary data to store, and these frequency entries can be safely omitted, their presence does not invalidate the data format and it may be simpler to use a more naive algorithm when producing the frequency tables.

The above tables are encoded as:

0x00 0x61 0x00	0x8f 0xff	# '\0' context # a <4095> # end of Order-0 table
0x61		# 'a' context
0x61	0x82 0x86	# a <646>
0x62 0x02	0x86 0xbd	
	0x83 0x5e	- # c (implicit) <862>
	0x83 0x5e	# d (implicit) <862>
0x61	0x82 0x66	# a <614>
0x62 0x02	0x86 0x67	# b <+2: c,d> <1639>

~~~~~	~~~~~	0x83	0x33	# c (implicit) <819>
~~~~~	~~~~~	0x83	Oxff	# d (implicit) <1023>
0x00				<pre># end of Order-0 table</pre>
0x62	0x02			# 'b' context, <+2: c, d>
0x72		0x8f	Oxff	# r <4095>
0x00				<pre># end of Order-0 table</pre>
				<pre># 'c' context (implicit)</pre>
0x61		0x8f	Oxff	. u 1000
0x00				<pre># end of Order-0 table</pre>
				# (d) contout (implicit)
0x61		004	0xff	<pre># 'd' context (implicit) # a <4095></pre>
01101		0x81	UXII	. u 1000
0x00				<pre># end of Order-0 table</pre>
0x72				# 'r' context
0x61		0 v 8f	Oxff	
0x01		UNUI	OVII	# end of Order-0 table
ULUU				# end of order-0 table
0x00				# end of contexts

2.2 rANS entropy encoding

The encoder takes a symbol s and a current state x (initially L below) to produce a new state x' with function C.

x' = C(s, x)

The decoding function D is the inverse of C such that C(D(x)) = x.

D(x') = (s, x)

The entire encoded message can be viewed as a series of nested C operations, with decoding yielding the symbols in reverse order, much like popping items off a stack. This is where the asymmetric part of ANS comes from.

As we encode into x the value will grow, so for efficiency we ensure that it always fits within known bounds. This is governed by

 $L \leq x < bL - 1$

where b is the base and L is the lower-bound.

We ensure this property is true before every use of C and after every use of D. Finally to end the stream we flush any remaining data out by storing the end state of x.

Implementation specifics

We use an unsigned 32-bit integer to hold x. In encoding it is initialised to L. For decoding it is read little-endian from the input stream.

Recall $freq_i$ is the frequency of the *i*-th symbol s_i in alphabet A. We define $cfreq_i$ to be cumulative frequency of all symbols up to but not including s_i :

$$cfreq_i = \begin{cases} 0 & \text{if } i < 1\\ cfreq_{i-1} + freq_{i-1} & \text{if } i \ge 1 \end{cases}$$

We have a reverse lookup table $cfreq_to_sym_c$ from 0 to 4095 (0xfff) that maps a cumulative frequency c to a symbol s.

 $cfreq_to_sym_c = s_i$ where $c: cfreq_i \le c < cfreq_i + freq_i$

The x' = C(s, x) function used for the *i*-th symbol s is:

$$x' = (x/freq_i) \times 0x1000 + cfreq_i + (x \mod freq_i)$$

The D(x') = (s, x) function used to produce the *i*-th symbol s and a new state x is:
